

Problem 1

(10 pts) Ginerva Weasley is playing with the network given below. Help her calculate the number of paths from node 1 to node 14.

Hint: assume a “path” must have at least one edge in it to be well defined, and use dynamic programming to fill in a table that counts number of paths from each node j to 14, starting from 14 down to 1.

There are 30 paths from node 1 to to node 14. This was calculated by filling in the following table:

j	14	13	12	11	10	9	8	7	6	5	4	3	2	1
$X_{j,14}$	0	1	1	2	3	4	4	4	2	7	14	18	26	30

The above table was filled in from left to right. Starting at $j=14$: there are 0 paths from 14 to 14 because as the problem states, a path must have at least one edge in it to be well defined. The base cases in this dynamic programming table are the nodes 13 and 11, as they are immediate neighbors to 14. Every subsequent node can be calculated using the nodes already filled in. For example - 12 (the second node to be filled in) only has a path to node 13, which itself has 1 path to 14 thus there is only 1 path from 12 to 14. Similarly, there is a path from node 5 to nodes 6, 11, and 10 which each have 2, 2, and 3 paths to 14 respectively. This means there are $2 + 2 + 3 = 7$ paths from node 5 to node 14. Applying this logic for every node allows every path to 14 to be implicitly enumerated.

Problem 2

(10 pts) Ginny Weasley needs your help with her wizardly homework. Shes trying to come up with an example of a directed graph $G = (V, E)$, a start vertex $s \in V$ and a set of tree edges $E_T \subseteq E$ such that for each vertex $v \in V$, the unique path in the graph (V, E_T) from s to v is a shortest path in G , yet the set of edges E_T cannot be produced by running a depth-first search on G , no matter how the vertices are ordered in each adjacency list. Include an explanation of why your example satisfies the requirements.

Consider the following graph G , set of tree edges E_T , and starting vertex s :

There are only 2 different paths that DFS could take from s to explore the entire graph. Here are visualizations of these paths using the notation for timestamps (d/f) from CLRS.¹

Both paths leave out one of the edges in E_T .

¹Forgive my MSPaint skills

Problem 3

(15 pts) Prof. Dumbledore needs your help to compute the in- and out-degrees of all vertices in a directed multigraph G . However, he is not sure how to represent the graph so that the calculation is most efficient. For each of the three possible representations, express your answers in asymptotic notation (the only notation Dumbledore understands), in terms of V and E , and justify your claim.

(a) An **adjacency matrix** representation. Assume the size of the matrix is known.

$\Theta(|V|^2 = n^2)$ - In order to calculate the degree of all nodes, you would need to visit each row of the matrix $\text{adj}[i][*]$, and scan across all of the entries ($\text{adj}[i][j]$) in order to calculate (the degree for $V[i]$) =

$$d(V[i]) = \sum_{j=0}^{|E|=m} (\text{adj}[i][j] = \sum [w(i, j) \forall (V_i, V_j) \in E] - \sum [w(j, i) \forall (V_j, V_i) \in E])$$

(which is a constant time operation, assuming the matrix is precalculated² and G is a directed graph³).

(b) An **edge list** representation. Assume vertices have arbitrary labels.

TODO

(c) An **adjacency list** representation. Assume the vectors length is known.

TODO

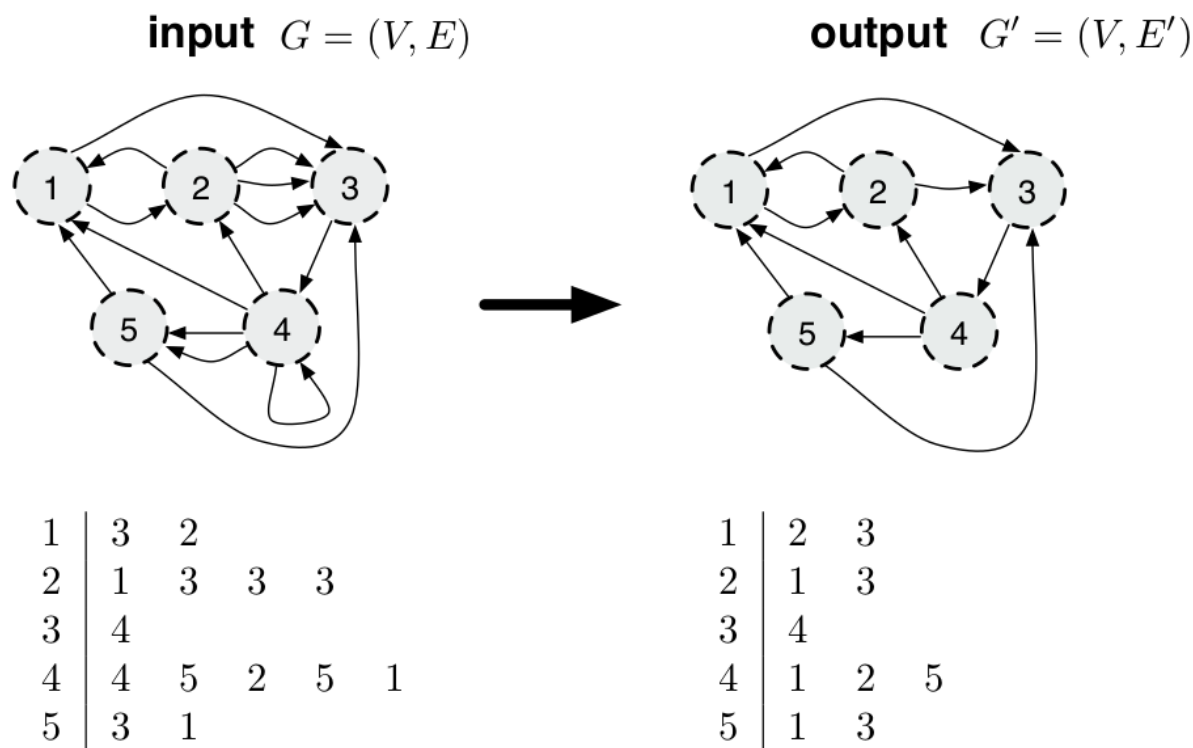

²Calculating this matrix with that formula would take $\Theta(2|E||V|^2)$ time

³The direction of the edge can be assumed : $(V_i, V_j) \implies$ there is an edge from V_i to V_j

Problem 4

(30 pts) Deep in the heart of the Hogwarts School of Witchcraft and Wizardry, there lies a magical grey parrot that demands that any challenger efficiently convert directed multigraphs into directed simple graphs. If the wizard can correctly solve a series of arbitrary instances of this problem, the parrot will unlock a secret passageway.

Let $G = (E, V)$ denote a directed multigraph. A directed simple graph is a $G' = (V, E')$, such that E' is derived from the edges in E so that (i) every directed multiedge, e.g., $(u, v), (u, v)$ or even simply (u, v) , has been replaced by a single directed edge (u, v) and (ii) all self-loops (u, u) have been removed.

An example of transforming $G \rightarrow G'$

Describe and analyze an algorithm (explain how it works, give pseudocode if necessary, derive its running time and space usage, and prove its correctness) that takes $O(V + E)$ time and space to convert G into G' , and thereby will solve any of the Sphinx questions. Assume both G and G' are stored as adjacency lists.

Hermiones hints: Don't assume adjacencies $\text{Adj}[u]$ are ordered in any particular way, and remember that you can add edges to the list and then remove ones you don't need.

TODO

Problem 5

(15 pts extra credit) Professor McGonagall has provided the young wizard Ron with three magical batteries whose sizes are 42, 27, and 16 morts, respectively. (A mort is a unit of wizard energy.) The 27-mort and 16-mort batteries are fully charged (containing 27 and 16 morts of energy, respectively), while the 42-mort battery is empty, with 0 morts. McGonagall says that Ron is only allowed to use, repeatedly, if necessary, the **mort transfer spell** when working with these batteries. This spell transfers all the morts in one battery to another battery, and it halts the transfer either when the source battery has no morts remaining or when the destination battery is fully charged (whichever comes first).

McGonagall challenges Ron to determine whether there exists a sequence of mort-transfer spells that leaves exactly 12 morts either in the 27-mort or in the 16-mort battery.

- (a) Ron knows this is actually a graph problem. Give a precise definition of how to model this problem as a graph, and state the specific question about this graph that must be answered.

TODO

- (b) What algorithm should Ron apply to solve the graph problem?

TODO

- (c) Apply that algorithm to McGonagall's question. Report and justify your answer.

TODO
